

Hybrid Fusion Power Station

Overview

Hybrid nuclear fusion–fission (hybrid nuclear power) is a proposed means of generating power by use of a combination of nuclear fusion and fission processes. The basic idea is to use high-energy fast neutrons from a fusion reactor to trigger fission in non-fissile fuels like U-238 or Th-232. Each neutron can.

The concept dates to the 1950s, and was strongly advocated by during the 1970s. At that time the first powerful fusion experiments were being built, but it would still be many.

Through the early development of the hybrid concept, the question of overall economics appeared difficult to answer. A series of studies.

The surrounding blanket can be a material (enriched uranium or) or a fertile material (capable of conversion into a fissionable material by neutron bombardment) such as .

There are three main components to the hybrid fusion fuel cycle: , , and fissionable elements. Deuterium can be derived by the separation of hydrogen isotopes in seawater.

Fission basicsConventional rely on a of events that release two or three neutrons that cause further fission events. By careful arrangement and the use of various absorber.

The fusion process alone currently does not achieve sufficient gain (power output over power input) to be viable as a power source. By using the.

In contrast to current commercial fission reactors, hybrid reactors potentially demonstrate what is considered behavior.
